

Space X Falcon 9 First Stage Landing Prediction

Hands on Lab: Complete the Machine Learning Prediction lab

Estimated time needed: 60 minutes

Space X advertises Falcon 9 rocket launches on its website with a cost of 62 million dollars; other providers cost upward of 165 million dollars each, much of the savings is because Space X can reuse the first stage. Therefore if we can determine if the first stage will land, we can determine the cost of a launch. This information can be used if an alternate company wants to bid against space X for a rocket launch. In this lab, you will create a machine learning pipeline to predict if the first stage will land given the data from the preceding labs.

Several examples of an unsuccessful landing are shown here:

Most unsuccessful landings are planed. Space X; performs a controlled landing in the oceans.

Objectives

Perform exploratory Data Analysis and determine Training Labels

- create a column for the class
- Standardize the data
- · Split into training data and test data

-Find best Hyperparameter for SVM, Classification Trees and Logistic Regression

- Find the method performs best using test data
- Import Libraries and Define Auxiliary Functions

```

```

We will import the following libraries for the lab

```
1 # Pandas is a software library written for the Python programming language for data manipulation and analysis.
 2 import pandas as pd
 3 # NumPy is a library for the Python programming language, adding support for large, multi-dimensional arrays and matrices, al
 4 import numpy as np
 5 # Matplotlib is a plotting library for python and pyplot gives us a MatLab like plotting framework. We will use this in our p
 6 import matplotlib.pyplot as plt
 7 #Seaborn is a Python data visualization library based on matplotlib. It provides a high-level interface for drawing attractiv
 8 import seaborn as sns
 9 # Preprocessing allows us to standarsize our data
10 from sklearn import preprocessing
11 # Allows us to split our data into training and testing data
12 from sklearn.model_selection import train_test_split
13 # Allows us to test parameters of classification algorithms and find the best one
14 from sklearn.model_selection import GridSearchCV
15 # Logistic Regression classification algorithm
16 from sklearn.linear_model import LogisticRegression
17 # Support Vector Machine classification algorithm
18 from sklearn.svm import SVC
19 # Decision Tree classification algorithm
20 from sklearn.tree import DecisionTreeClassifier
21 # K Nearest Neighbors classification algorithm
22 from sklearn.neighbors import KNeighborsClassifier
```

This function is to plot the confusion matrix.

```
1 def plot_confusion_matrix(y,y_predict):
       "this function plots the confusion matrix"
      from sklearn.metrics import confusion_matrix
 3
 4
 5
      cm = confusion_matrix(y, y_predict)
 6
      ax= plt.subplot()
 7
      sns.heatmap(cm, annot=True, ax = ax); #annot=True to annotate cells
      ax.set_xlabel('Predicted labels')
8
g
      ax.set ylabel('True labels')
10
      ax.set title('Confusion Matrix');
      ax.xaxis.set_ticklabels(['did not land', 'land']); ax.yaxis.set_ticklabels(['did not land', 'landed'])
11
12
      plt.show()
```

Load the dataframe

TASK 1

Create a NumPy array from the column Class in data, by applying the method to_numpy() then assign it to the variable Y,make sure the output is a Pandas series (only one bracket df['name of column']).

1 Y = data['Class'].to_numpy()

TASK 2

Standardize the data in X then reassign it to the variable X using the transform provided below.

```
1 transform = preprocessing.StandardScaler()
2 X = transform.fit_transform(X)
```

We split the data into training and testing data using the function train_test_split. The training data is divided into validation data, a second set used for training data; then the models are trained and hyperparameters are selected using the function GridSearchCV.

TASK 3

Use the function train_test_split to split the data X and Y into training and test data. Set the parameter test_size to 0.2 and random_state to 2. The training data and test data should be assigned to the following labels.

```
X_train, X_test, Y_train, Y_test

1 X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=0.2, random_state=2)
we can see we only have 18 test samples.

1 Y_test.shape

> (18,)
```

TASK 4

Create a logistic regression object then create a GridSearchCV object logreg_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

We output the GridSearchCV object for logistic regression. We display the best parameters using the data attribute best_params_ and the accuracy on the validation data using the data attribute best_score_.

```
1 print("tuned hpyerparameters :(best parameters) ",logreg_cv.best_params_)
2 print("accuracy :",logreg_cv.best_score_)

tuned hpyerparameters :(best parameters) {'C': 0.01, 'penalty': 'l2', 'solver': 'lbfgs'}
accuracy : 0.8464285714285713
```

TASK 5

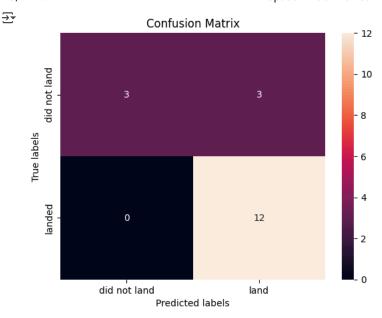

Calculate the accuracy on the test data using the method score:

```
1 logreg_cv.score(X_test, Y_test)

→ 0.8333333333333334
```

Lets look at the confusion matrix:

```
1 yhat=logreg_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```

Examining the confusion matrix, we see that logistic regression can distinguish between the different classes. We see that the problem is false positives.

Overview:

True Postive - 12 (True label is landed, Predicted label is also landed)

False Postive - 3 (True label is not landed, Predicted label is landed)

TASK 6

Create a support vector machine object then create a GridSearchCV object svm_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

 ${f 1}$ Comienza a programar o ${\underline{\sf generar}}$ con IA.

```
1 print("tuned hpyerparameters :(best parameters) ",svm_cv.best_params_)
2 print("accuracy :",svm_cv.best_score_)
```

tuned hpyerparameters :(best parameters) {'C': np.float64(1.0), 'gamma': np.float64(0.03162277660168379), 'kernel': 'sigmoi accuracy : 0.8482142857142856

TASK 7

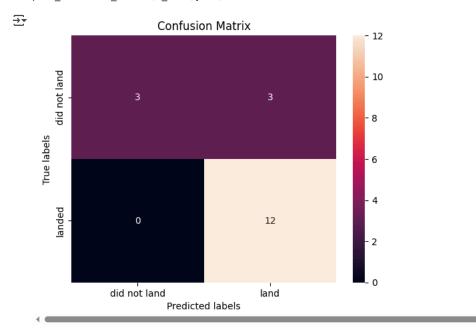

Calculate the accuracy on the test data using the method score:

```
1 svm_cv = GridSearchCV(svm, parameters, cv=10)
2 svm_cv.fit(X_train, Y_train)
```

We can plot the confusion matrix

```
1 yhat=svm_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```

TASK 8

Create a decision tree classifier object then create a GridSearchCV object tree_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

```
1 parameters = {'criterion': ['gini', 'entropy'],
2     'splitter': ['best', 'random'],
3     'max_depth': [2*n for n in range(1,10)],
4     'max_features': ['auto', 'sqrt'],
5     'min_samples_leaf': [1, 2, 4],
6     'min_samples_split': [2, 5, 10]}
7
8 tree = DecisionTreeClassifier()

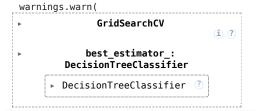

1 tree_cv = GridSearchCV(tree, parameters, cv=10)
2 tree_cv.fit(X_train, Y_train)
```

```
/usr/local/lib/python3.11/dist-packages/sklearn/model selection/ validation.py:528: FitFailedWarning:
3240 fits failed out of a total of 6480.
The score on these train-test partitions for these parameters will be set to nan.
If these failures are not expected, you can try to debug them by setting error_score='raise'.

```
1 print("tuned hpyerparameters :(best parameters) ",tree_cv.best_params_)
2 print("accuracy :",tree_cv.best_score_)

tuned hpyerparameters :(best parameters) {'criterion': 'gini', 'max_depth': 4, 'max_features': 'sqrt', 'min_samples_leaf': accuracy : 0.8892857142857145
```

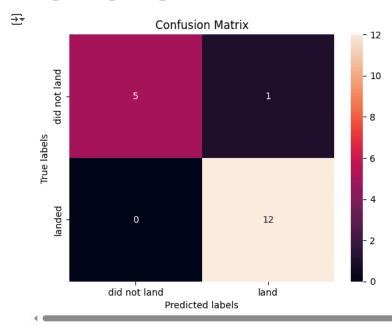

TASK 9

Calculate the accuracy of tree_cv on the test data using the method score:

```
1 tree_cv.score(X_test, Y_test)
2
```

We can plot the confusion matrix

```
1 yhat = tree_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```

TASK 10

Create a k nearest neighbors object then create a GridSearchCV object knn_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.
